Message from the APIEMS President

Greeting and a warm welcome to the participants of the 15th Asia Pacific Industrial Engineering and Management Systems Conference. Started in 1998, APIEMS has grown to become the premier conference for industrial engineering and management systems in the region with participants from all around the world. The main theme of this year conference: “Sustainable Industrial Systems and Big Data Management”, is an attempt to address the balance among economic and technical development, social development, and environmental protection in this fast changing world.

I congratulate and thank Prof. Dr. Chi-Hyuck Jun, the conference chair, whose leadership made this APIEMS 2014 conference possible. We are also grateful for the enthusiastic support of APIEMS from the KIIE and the Korea research community.

On behalf of the Asia Pacific Industrial Engineering and Management Society, I wish you a successful conference with many thoughtful discussions and debates with old and new friends.

Message from the General Chair

Welcome to APIEMS 2014 in Jeju City, a beautiful island located at the most south of Korea. It is our great pleasure to organize this conference, which is supported by Korean Institute of Industrial Engineers (KIIE). APIEMS conferences have rapidly emerged as an important forum for exchange of ideas and information about latest developments in the field of industrial engineering and management systems among professionals mostly from Asia-Pacific countries. APIEMS 2014 conference encourages contributors to address the topical theme: Sustainable Industrial Systems and Big Data Management. Papers will represent the latest academic thinking and successful case examples. The wider audience will benefit from the knowledge and experience of leading practitioners and academics in this area.

The conference seeks research contributions from researchers, educators, modelers, software developers, users and practitioners. We hope that you enjoy participating in APIEMS 2014 and staying in Jeju.

Abstract. PT. Tirta Nusantara Intimizu produces manufacturing industrial water pumps. Some parts of the water pump are produced at PT. Intimizu Tirta Nusantara, but there are some parts that come from suppliers within and outside of the country. The parts that are ready to be assembled on the assembly line but not smooth and many line stop in the assembly process become a major problem. It makes the time -consuming process of assembly process takes a long time. Therefore, to solve this problem which used several methods of line balancing are a Kilbridge Wester method, Helgeson Birnie method, J – Wagon method, and Moodie Young Method by time study and raw material management. The aim of these methods for assembly line is how to reduce the processing time on the assembly line. The current condition showed that the equilibrium line amounted to only 63.89 %, 36.11 % for the balanced delay, smoothness index of 124.61, and has a production capacity of only 2411 units per month. After using the Moodie Young method the company obtains the higher efficiency of 84.57 %, balanced delay of 15:43 %, smoothness index of 52.21, and increase the production capacity of 2411 units per month to 2593 units per month.

1. INTRODUCTION

PT. Tirta Intimizu Nusantara (TIN) is one of the manufacturing companies in Indonesia which is engaged in the field of water pumps. At the beginning PT. Intimizu Tirta Nusantara has been producing water pump as the main product, but after that some kind of water pump is produced to fulfill the needs of the people of Indonesia and export. PT. TIN still has some problems, especially with some elements of the work station at the assembly line. This has an impact on productivity is hampered and can't meet the sales planning targets.

In this research, discussing and analyzing the balancing line on the water pump type PC-250 BIT at PT. Intimizu Tirta Nusantara. The goal of this research is how to increase the production capacity and improve the line efficiency. In addition, it is expected to reduce the delay time and the bottleneck activities that occur on the assembly line too. The methods are used in this study are the Kilbridge Wester Method, Helgeson Birnie

Method, J-Wagon Methods, and Moodie Young Method.

2. LITERATURE STUDY

The line balancing method for job assignment is related to each other work stations in a production line where each station has a processing time that does not exceed the cycle time of each work stations. In general, planning for line balancing includes efforts to achieve an optimal capacity, which does not happen if there is too much idle time. It is interconnected between the jobs assignment and labors assignment. Therefore, the activities relationship is described with a relationship diagrams (precedence diagram), while the relationship between jobs is called job precedence or precedence network.

Time of each work element is obtained from the initial calculations of motion time with normality test, uniformity test and adequacy of the data. Once the data is otherwise normal, pretty

uniform and subsequent, then calculate the normal time from standard time of each work element. Calculation of the normal time and standard time as below equation [Sutalaksana, 2006]:

$$\text{Normal Time} = \frac{\text{Average time measurement}}{\text{performance rating}} \quad (1)$$

$$\text{Standard time} = \text{Normal time} (1 + \text{Allowance}) \quad (2)$$

According to Kusnadi (2009), the cycle time is defined as the time required to produce one unit of product, in this case determined from the longest process (bottleneck), whether it is human or machine work. This will determine each method, the value of the cycle time to be obtained.

2.1. Line Balancing

According to Gasperz (2000), line balancing is a balancing task assignment with work station elements in assembly line to minimize the amount of work station and minimize the total idle time on all stations for a certain level of output, which in this line balancing the processing time per unit of product at specified for each task and the sequential relationship should be considered.

2.2. Kilbridge-Wester Heuristic Method

Kilbridge-Wester is a method designed by M.Kilbridge and L.Wester as another approach to overcome the problems of equilibrium line [Irfan, 2010]. In this method, the performance of grouping elements into groups that have the same level of connectedness. The steps used method Kilbridge-Wester are as follows:

- Produce the *precedence diagram from the problems*.
- Grouping the precedence from left to the right in coloumn area
- Grouping elements in many ways to reach the best grouping which has a best or almost the same time with the cycle time.
- If any elements of work station have no grouping yet and the grouping time is less the cycle time, continue to group with the element in the next precedence.
- Continue the grouping process until all the elements are grouped.

2.3. Helgeson-Birnie Method

This method more popular than as the the Ranked Positional-Weight Technique because this technique using ranked to make group elements and suggested by Helgeson and Birnie [Bedworth, 1987]. The steps in this method are as follows [Irfan, 2010]:

- Create a precedence diagram for each process.

- Determine the weight of the position for each element of work related to the operation time for the longest processing time from the beginning to the rest of the starting operation after operation.
- Rank each processing element is based on the weight of the position in step 2. Workmanship which has the greatest weight is placed on the first rank.
- Determine the cycle time (CT).
- Select the operating element with utmost weight i, allocated to a work station. If still viable, time station (ST) <(CT), allocate operation with the next highest weight, but this location should not make time station > CT.
- If the allocation of a station operating elements make time > CT, then the rest of the time (CT - ST) is filled with the allocation of the operating element with the greatest weight and the addition does not make ST <CT.
- If the operating element that allocated to make ST <CT is not there, go back to step e.

2.4. J-Wagon Method

This method prioritizes the highest number of work elements, where the elements of the work will be prioritized in advance to be placed in a work station and was followed by work elements that have the smallest number of work elements (Aquilano & Chase, 407). Here are the steps of J-Wagon method:

- Calculate the summary of work elements from each operation base on number of operation time from precedence network.
- Rank the operation base on the biggest number of operation time
- Alocate the operation which has the beginning position from all the precedence diagram.
- Alocate the operation to the whole station.
- Alocate all station which total processing time not more than certain C_T (Cycle Time).

2.5. Moodie Young Method

Moodie Young method has two stages of analysis. Phase (phase) of the work station is made by grouping matrix elements of the relationship between work, such methods are not ranked like Helgeson-Birnie method. Phase two, to revise the results of phase one [Irfan, 2010].

Phase one: Elements of workmanship placed on successive work stations in assembly lines using Largest-candidate rules. Largest-candidate rule consists of the placement of the elements for the purpose of reduction of time. From here, when the two elements work are enough to be placed in the station, one of which with a larger time placed first. Purpose of placement for each element is to reduce the time for next arrangement. For example, matrix P indicates precursor workmanship of each element

and the matrix F workmanship followers for each element for each assignment procedure.

Phase two: In phase two, trying to distribute idle time (idle) evenly (same) for each station. The steps in step two are as follows:

- Determine the two elements of the shortest and longest time of rebalancing phase one station.
- Determine the half of differences between the two goal value
- $GOAL = (ST_{max} - ST_{min}) / 2$. (3)
- Determine single element in ST_{max} which is less than two goal value and not more than predecessor element
- Determine all the possible exchange of ST_{max} with single element of ST_{min} which reducing ST_{max} and get ST_{min} will smaller than 2 x GOAL Value.
- Perform onsite indicated by the candidate with the smallest absolute difference between the candidates with GOAL value.
- If there is no exchange or transfer is possible between the largest and smallest station, seeking exchange between rank on the following work: N (station N has ranked the greatest amount of idle time), N-1, N-2, N-3, ..., 3, 2, 1.

If exchange is not possible, do the restrictions on the value of GOAL and repeat steps a to f.

2.6. Line Balancing Evaluation

Trying to apply the method of line balancing, take a few steps. The steps that should be performed include:

- Collect data about the target output production each day and working hour per day.
- Collect data about jobs, number or production, working time for each element in production.
- Make the network of fabric cutting, sewing and packing.
- Calculate the cycle time with below equation:

$$CT = \frac{\text{Working hour per year (second)}}{\text{Demand per year (pcs)}} \quad (4)$$

- Calculate the minimal number of work elements (N) with equation:

$$N = \frac{\text{Total time of working element (second)}}{\text{cycle time (second)}} \quad (5)$$

- Applying each line balance method, these three methods are used such as Kilbridge-Wester Heuristic methods, Helgeson-Birnie method and Moodie Young method.
- After all of the calculation from each method, calculate the line efficiency with equation [Baroto, 2004]:

$$LE = \frac{\sum TSi}{(K)(CT)} \times 100\% \quad (6)$$

Which:

TSi = Work element time -i

K = Total number of work element

CT = Longest cycle time

- Then calculate the balance delay (Balance Delay). Balance Delay is a measure of the inefficiency of the resulting trajectory of the actual time unemployed due to imperfect allocation between workstations. Balance Delay can be formulated as follows [Baroto, 2004]:

$$BD = 100\% - LE \quad (7)$$

- Smoothness Index is an index showing the relative smoothness of specific assembly line balancing. Furthermore Smoothness Index can be calculated by the formula:

$$SI = \sqrt{\sum (TSi_{max} - TSi)^2} \quad (8)$$

- This calculation results will be analyzed with the descriptive and the comparison with the original factory condition. So it can be applied to a method that improved its efficiency line of factory.
